

Untitled

Data Wrangling

For the interest of space, codes in this section will not be shown. Yet they are available in the .rmd file.

Read in the data

The data were collected across years 2022 (CARE panel, n=218) and 2023 (Students joining an avalanche course, n=59).

Combine 2022 and 2023 data

They were combined into one data set ($n = 277$). An index variable was generated as the unique identifier for each case.

Remove cases

Remove careless responses (according to attention trap)

Q10_2 and Q10_5, as well as Q19_1 and Q19_4 were same questions with different wordings. If the responses had conflicting results between them, they would be regarded as careless responses and hence deleted ($n = 24$).

Remove cases who did not consent

Respondents who did not consent to participate were removed from the data ($n = 4$).

Remove cases with NA for if having a leader

Respondents who did not disclose if the ski group had a leader were removed from the data ($n = 27$).

Replace value of -99 with NA

-99 was used to label seen but unanswered questions. They were relabeled as NA.

Unify value labels

Values of some of the variables had been inconsistently labeled by Qualtrics. They were unified here.

Relabel variables

Properly label the variables so that the interpretation can be better managed. For the label, see Table 1.

Unify the direction of item wording

Four items of the SOCIAL were worded in negative direction (e.g. XXXX). Basic factor analysis attempts to identify latent variance through exploring the **co-variance** in measured variables. As such, the direction of the item wording (positive vs negative) does not influence the analysis. However, we still unify the results into same wording direction (positive) for the interest of easy interpretation.

Generate Norwegian variable labels

The survey was carried out in Norwegian and the initial language of text is Norwegian. Norwegian labels were created here.

Create data sets for analysis

Four data sets were created. They are a. 18 item with leader; b. 6 item with leader; c. 17 item without leader; d. 5 item without leader; 3. background. The case identifier is “index” variable across data sets.

Create with-leader and without-leader data-sets

Before generating 4 data sets, the data were first separated according to with ($n = 104$) or with-out leader ($n = 118$).

Remove cases with 50% NAs across major questions for each data sets

Within in each data set (with/without leader), cases with 50% NAs were removed from data. Three cases (#213,253,276) were removed from with-leader group; Four cases (#94, 252, 258, 275) were removed from without-leader group.

Create data set: 17 item without leader

Without-leader group respondents answered 22 out of 26 questions in the survey (the remaining 4 questions were about leader). Within the 22 questions, 17 were adapted from Zeiweiful’s long version, 5 were from short version. They were further split into two data sets. They were subsequently referred to as without-leader long and without-leader short, respectively. The sample size is 114. According the publications, the minimum sample size for an exploratory factor analysis should be $5 \times (\text{number of items})$. In our case, the

without-leader group's long version analysis involves 17 items, indicating at least $17 \times 5 = 85$ samples. Our sample size meets this requirement.

Create data set: 5 item without leader

According the publications, the minimum sample size for an exploratory factor analysis should be $5 \times (\text{number of items})$. In our case, the without-leader group's long version analysis involves 5 items, indicating at least $5 \times 5 = 25$ samples. Our sample size meets this requirement.

Create data set: 20 item with leader

Without-leader group respondents answered all 26 questions in the survey. Among the questions, 20 were adapted from Zeiweiful's long version, 6 were from short version. They were further split into two data sets. They were subsequently referred to as with-leader long and with-leader short, respectively. The sample size is 101. According the publications, the minimum sample size for an exploratory factor analysis should be $5 \times (\text{number of items})$. In our case, the without-leader group's long version analysis involves 20 items, indicating at least $20 \times 5 = 100$ samples. Our sample size meets this requirement.

Create data set: 6 item with leader

According the publications, the minimum sample size for an exploratory factor analysis should be $5 \times (\text{number of items})$. In our case, the without-leader group's long version analysis involves 5 items, indicating at least $6 \times 5 = 30$ samples. Our sample size meets this requirement.

Check and impute NAs and IDNs

Discriptive statistics with number of NAs and IDNs for each item

Table 1: Descriptive statistics for with-leader group (long)

	var	Question	n*	n of IDN†	n of NA	Central tendency		Dispers

i_anom0	Social interactions in the group negatively impacted decision	113	3	1	4.3	5.0	1.0

* number of cases minus number of NA

† IDN: Don't know

Adress NA and IDN casewise

The number of NAs and IDNs were few in number comparing with the sample size for each data set. Hence, the NAs and IDNs were checked case-wise, and decisions for each case were made accordingly. Please go to file “NA_and_IDN.md” for full description. A quick summary here: case #82 (in without group) were removed due to high proportion of IDNs, while other cases with NAs/IDNs does not show much logical issue. These NAs/IDNs will be imputed by within-subgroup median.

Sumarize data clensing

The full processes of data cleansing were summarized in the following flowchart.

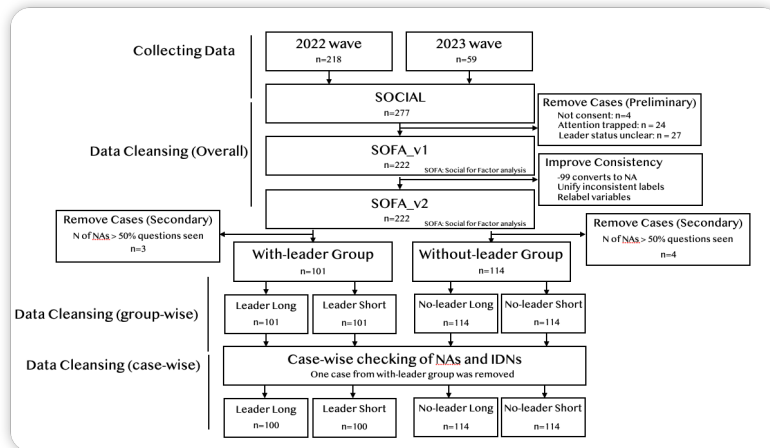

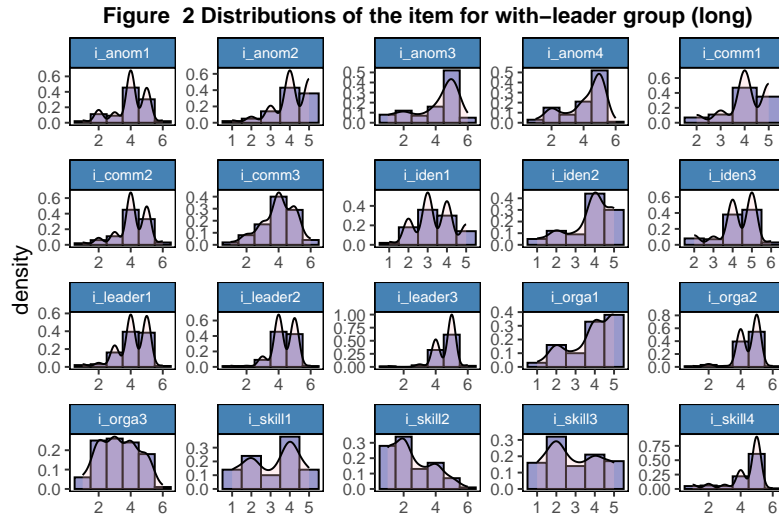

Figure 1: Flowchart for data cleansing

Visualization

Distribution

Since the data were collected from Likert scale, which usually skewed towards an end, I do not seek normality from

these graphs. Instead, I scanned through the distributions to get a sense of the features of each item, such as left skewness (e.g. i_anom3), right skewness (e.g. i_skill4), kurtosis (e.g. i_orga3), polarization (e.g. i_skill3). These also shed light on skiers' overall performance pattern across sub-groups. To illustrate, it could be interesting to find that the organization of without-leader group wasn't rated notably lower than that of with-leader group. However, the skills were rated higher in without-leader group. This indicates people who ski without a leader are more confident in his and his teammates skiing/avalanche-forecasting skills. Of course, I hope for a normal distribution from the factor scores obtained by the following factor analysis.

Correlation matrix

Correlation matrix was created for each of the four scales (2 long and 2 short). Pearson correlation coefficients were reported. Any coefficients ≥ 0.3 were highlighted in green circle; any coefficients ≥ 0.3 were highlighted in read circle.

There are several well-recognized criteria for checking factorability, including correlation matrix, KMO test, and Bartlett sphericity test. Here I checked the correlation. Other criteria

Figure 3 Distributions of the item for without-leader group (long)

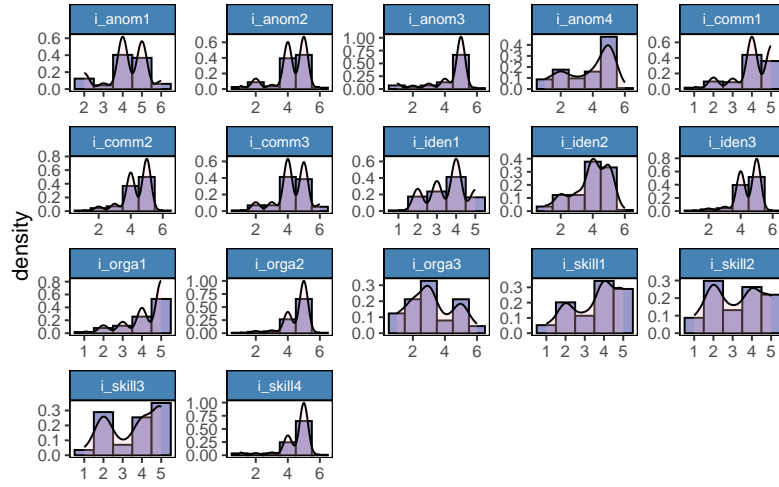

Figure 4 Distributions of the item for with-leader group (shc

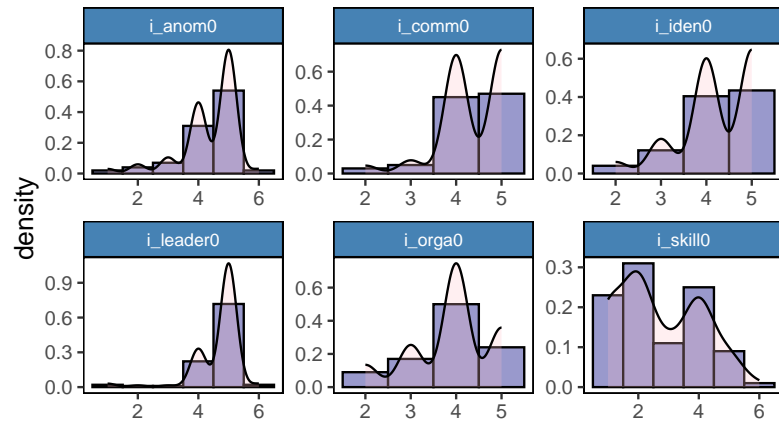

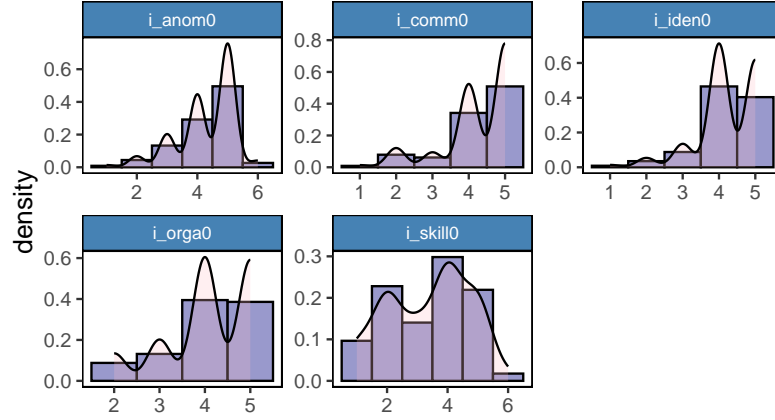

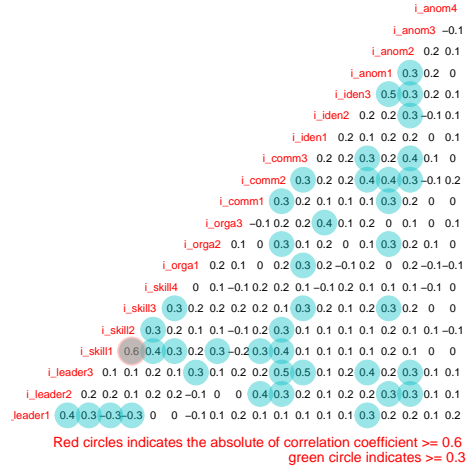

Figure 5 Distributions of the item for without-leader group (st

were checked in the following section. We hope that the majority of the items have a correlation coefficient ≥ 0.3 with at least one other item, which suggest good factorability.

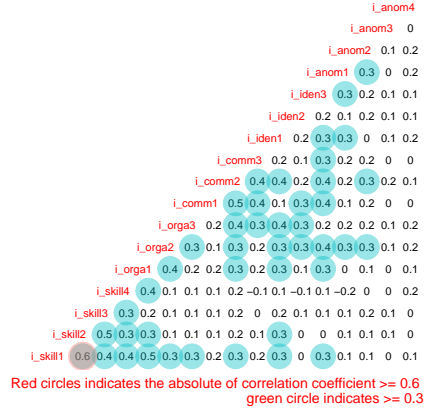

For with-leader group (long), it was observed that 18 of the 20 items correlated at least .3 with at least one other item, suggesting reasonable factorability. See figure 6.

Figure 6 Correlation matrix of the item for with-leader group (long)

For without-leader group (long), it was observed that 16 of the 17 items correlated at least .3 with at least one other item, suggesting reasonable factorability. See figure 7.

Figure 7 Correlation matrix of the item for without-leader group (long)

For with-leader group (short), it was observed that 6 of the 6 items correlated at least .3 with at least one other item, suggesting reasonable factorability. See figure 8.

Figure 8 Correlation matrix of the item for with-leader group (short)

For without-leader group (short), it was observed that 6 of the 6 items correlated at least .3 with at least one other item, suggesting reasonable factorability. See figure 9.

i_iden0	0.53	0.48
i_anom0	0.721	

VSS complexity 1 achieves a maximum of 0.83 with 1 factors
VSS complexity 2 achieves a maximum of 0.89 with 2 factors
The Velicer MAP achieves a minimum of 0.08 with 1 factors
Empirical BIC achieves a minimum of -16.67 with 1 factors
Sample Size adjusted BIC achieves a minimum of 0.44 with 2 factors
